

Raw Input = Latest News (text) from each source

Normalized output = Graphs with entities and relationships

1 Graph = Combine individual graphs from each source into a single graph representing latest updates.

The delta calculator must compare the "1 Graph" representing the latest updates with the previous / last saved graph and:

- Produce impact report outlining what changed
- Apply latest updates to graph

Re normalization: we classify raw text to keywords during this time.

E.g., "Strait of Hormuz" story ----- matches -----> oil
 ----- matches -----> shipping

At the end, have UI that allows you to type in term like "oil" and get back (from current graph) what to invest in vs. avoid like hell
